

S.S.S. (The Super Smart Scheduler)

Members: Balledo, Coronel, Rivera

Project Description:

Try to imagine yourself as a scholar reviewing for your Final Exam in Biology. You have 5 days left, and you need to review two 1000-page textbooks. And to add onto that, you also have 3 projects due then as well. Many students deal with tons and tons of schoolwork to do, so much so that most of them resort to cramming and all-nighters. This can really affect a student's mental health. Cramming usually occurs when a person has poor time-management, but it can be really difficult to manage your time as many apps require you to manually update events constantly, which can be tedious. To add to that, multiple date-tracking apps tend to have complex layouts, which could confuse the user.

Project Objectives:

What our code wants to focus on is to create a simple date-tracker that not only makes it easy to input the necessary and erase the data that isn't needed anymore, but it will also hopefully motivate the user to be productive.

Features of our project:

Our code is essentially a point-based system that can display in two different ways: it can either display activities based on the date entered, or it could also enter based on the level of importance, meaning it will display the activities due first. This means we will feature the following: an ***add*** feature that inputs the date and title of said work from the user. This will then be saved to two different features: the ***list*** feature and the ***schedule*** feature. The former feature mentioned above displays the list of activities present, having no particular order. And our latter feature displays both the date and the title of the activity, displaying it in the order of which activities come first. Aside from that, there will also be a ***check off task*** feature. This will allow the user to check off an activity that has already been completed.

The requirements:

What we intend the code to do is that it will first display a menu bar that will welcome the user. It will then display a list of options. Those options will be the features mentioned earlier, which are the following: 1. Add, 2. Schedule, 3. List, 4. Check off task, and 5. Exit code. The user will have to input the number of their choice, and depending on the answer of the user, it will either request input and process, or output. For the add feature, it will require the user a date of requirement and the title of the activity. When the user complies, it will be directed back to the code and will be saved. It will then be displayed when the user chooses either the schedule feature or the list feature with the format being stated in the features part of this proposal. If an activity is finished, the user can then choose the check off task and remove the said task.

Sample Output:

```
class task:
    def __init__(self,nt,wt,pt,dt,et):
        self.nt = name
        self.wt = what
        self.pt = prio
        self.dt = duedate
        self.et = estt

def add_task(nt,wt,pt,dt,et):
    new_slot=task(nt,wt,pt,dt,et)
    task_manager.append(new_slot)

task_manager=[]
choice=0
while choice !=5:

    print("Menu:\n 1. Add\n 2. Schedule\n 3. List\n 4. Check off task\n 5. Exit\n")
    choice=int(input("Choice: "))

    if choice==1:
```

```
name=str(input("Enter task name: \n"))
what=str(input("Type (Assignment, Project, Exam, Quiz): \n"))
prio=int(input("Priority-from lowest to highest (1-5): \n"))
duedate=int(input("Due in (days): \n"))
estt=int(input("Estimated minutes needed to finish: \n"))

add_task(name,what,prio,duedate,estt)

# beyond this is all TESTS.
index = task_manager[0]
print(index.nt)
```
